Report

Saktaganov Ramazan | CS 2602

Students and staff receive messages about classes, accounts or payments that may imitate university notices. A suspicious email can request a password or include a link or attachment.

Unsure where to report it, a person may ignore or delete it, delaying the university's response [1]. UniSafe is a proposed web service that gives students and staff a clear way to report suspicious messages and other cyber incidents.

Users choose an incident type, describe what happened, add the date, optionally attach a screenshot, review the details and submit. The service should confirm receipt with a reference number, allow status checks, provide safety advice and show an alternative contact during outages. In the proposed system, a browser sends the report over HTTPS to a university server. The server validates and stores it in a restricted database for authorized IT or security staff. Staff review reports and decide whether follow-up is needed [2]; UniSafe does not automatically classify threats. The interactive prototype uses HTML, CSS and JavaScript to demonstrate report, review, confirmation, error and status screens. It is front-end only: it does not send real reports or upload files. A production version would need server-side validation, protected file storage and access controls [3].
